Introduction
A newly identified disease has killed large numbers of mature ‘ōhi’a trees (Metrosideros polymorpha) in forests and residential areas of the Puna and Hilo Districts of Hawai’i Island. Landowners have observed that when previously healthy-looking trees begin to exhibit symptoms they typically die within a matter of weeks. Pathogenicity tests conducted by the USDA Agriculture Research Service have determined that the causal agent of the disease is the vascular wilt fungus Ceratocystis fimbriata (Keith et al. 2015). Although Ceratocystis fimbriata has been present in Hawai’i as a pathogen of sweet potato for decades (Brown and Matsuura 1941), this is the first record of any Ceratocystis species affecting ‘ōhi’a. It is not yet known whether this widespread occurrence of ‘ōhi’a mortality results from an introduction of an exotic strain of the fungus or whether this constitutes a new host of an existing strain. This disease has the potential to kill ‘ōhi’a trees statewide.

Extent
The disease affects non-contiguous forest stands ranging from 1 to 100 acres. As of 2014, approximately 6,000 acres from Kalapana to Hilo on Hawai’i Island had stands showing greater than 50% mortality. The disease has not yet been reported on any of the other Hawaiian Islands.

Symptoms
Crowns of affected trees turn yellowish (chlorotic) and subsequently brown within days to weeks; dead leaves typically remain on branches for some time (Figure 1). On occasion, leaves of single branches or limbs of trees turn brown before the rest of the crown becomes brown (Figure 2). Recent investigation indicates that the pathogen progresses up the stem of the tree. Trees within a given stand appear to die in a haphazard pattern; the disease does not appear to radiate out from already-infected or dead trees. Within two to three years nearly 100% of trees in a stand succumb to the disease. Other trees and shrubs in the forest such as kōpiko (Psychotria spp.), ‘ohe mauka

Figure 1. Symptoms of Ceratocystis wilt of ‘ōhi’a include rapid browning of affected tree crowns.
(Polyscias spp.), strawberry guava (Psidium cattleianum), Melastoma spp., and Koster’s curse (Clidemia hirta) are not affected by the disease.

*Ceratocystis* manifests itself as dark, nearly black, staining in the sapwood along the outer margin of the trunks of affected trees. The stain is often radially distributed through the wood (Figures 3, 4, and 5). Wood samples incubated under moist conditions in plastic bags for a week produce characteristic fruiting bodies of *Ceratocystis* called perithecia (Figure 6). These fruiting bodies produce large numbers of spores whose transport accounts for subsequent infection of previously healthy ‘ōhi’a trees.

**Methods of Transmission**

It is not yet known how the disease spreads from tree to tree or from forest stand to forest stand. In other *Ceratocystis* plant hosts such as sweet potato, cacao, mango, and eucalyptus, the fungus is moved by insects, soil, water, infected cuttings, pruning wounds, or tools, and these modes of transmission may also be involved in infections of ‘ōhi’a trees and stands (Harrington n.d.). *Ceratocystis* has been found in soils under infected stands in Hawai‘i, as well as in frass (sawdust) produced by wood-boring beetles in infected trees. Contaminated soil, windblown frass, and infected wood may all transmit the disease.

**What to Do**

As of early 2015 the disease was confined to Hilo and the Puna district on Hawai‘i Island. Landowners who suspect *Ceratocystis* infection of ‘ōhi’a trees outside these areas are encouraged to contact Drs. Friday, Hughes, or Keith at the above addresses with reports and locations of infected areas. Digital photographs of crowns of infected trees and wood showing the characteristic staining will help in assessing likelihood of an infection.
Currently, there is no known method of protecting 'ōhi'a trees from becoming infected with Ceratocystis nor an effective treatment to cure trees that exhibit symptoms of the disease. To reduce the spread of Ceratocystis, landowners should not transport wood of affected 'ōhi'a trees to other areas. The pathogen may remain viable for over a year in dead wood. Tools used for cutting infected 'ōhi'a trees should be cleaned either with Lysol™ or a 70% rubbing alcohol solution. A freshly prepared 10% solution of chlorine bleach and water can be used as long as tools are oiled afterwards, as chlorine bleach will corrode metal tools. Chainsaw blades should be brushed clean, sprayed with cleaning solution, and run briefly to lubricate the chain. Vehicles used off-road in infected forest areas should be thoroughly cleaned underneath so as not to carry contaminated soil to healthy forests. Shoes, tools, and clothing used in infected forests should also be cleaned, especially before being used in healthy forests.

For more information and updates on research on Ceratocystis wilt of 'ōhi'a, see http://www.ohiawilt.org or scan the QR code.
